MARINE POLLUTION

Plastic waste inputs from land in Plastics in the marine environmente of 8 the ocean

Jenna R. Jambeck, 1* Roland Geyer, Chris Wilcox, Theodore R. Siegler, Miriam Perryman, ¹ Anthony Andrady, ⁵ Ramani Narayan, ⁶ Kara Lavender Law ⁷

Plastic debris in the marine environment is widely documented, but the quantity of plastic oits source and extremely difficult to remove entering the ocean from waste generated on land is unknown. By linking worldwide data on solid waste, population density, and economic status, we estimated the mass of land-based plastic waste entering the ocean. We calculate that 275 million metric duce inputs. tons (MT) of plastic waste was generated in 192 coastal countries in 2010, with 4.8 to 12.7 million MT entering the ocean. Population size and the quality of waste managementocean from waste generated by coastal popular systems largely determine which countries contribute the greatest mass of uncaptured waste available to become plastic marine debris. Without waste management infrastructure improvements, the cumulative quantity of plastic waste available to enter the ocean from land is predicted to increase by an order of magnitude by 2025.

orts of plastic pollution in the oceantons (MT)], based only on discharges from dualing enter the ocean via inland waterways, t appeared in the scientific literaturæsselsmilitary operationænd ship casualties wastewater outflows, and transport by wind or the early 1970s, yet more than 40 ƴఱ३rѣhe discharge of plastic from at-sea vesਫ਼ਫ਼ੀes. Estimates of the mass of plastic waste carer,no rigorous estimates exist of thehas since been banned (2), but losses still accedrby particular waterways range from <<1 kg unt and origin of plastic debris entt is widely cited that 80% of marine debris per day (Hilo, HI) to 4.2 MT (4200 kg) per day tering the marine environment 1975 the es- iginates from landhowever, this figure is not (Danube River) (10, 11). Because of their depentimated annual flux of litter of all materials weathsubstantiated and does not inform the detade on local watershed characteristics, these

from land-based sources.

Mass in 58% (61 out of 105) of countries with available data (5). available data (5).

and effects on the oceans, wildlife, and, poten ${ extstyle extst$ tially, humans (6). Plastic debris occurs on coallines, in Arctic sea iceat the sea surfacend on the sea floor (78). Weathering of lastic debris causes fragmentation into particles that even small marine invertebrates may ingest (9) Its small size also renders this debris untraceasile from open ocean environments, suggesting that the most effective mitigation strategies must $\begin{cases} \dot{\ensuremath{\mathbf{g}}} \ensuremath{\ensuremath{\mathbf{g}}} \ensuremat$

We estimated the annual input of plastic to tions worldwide. We defined mismanaged was as material that is either littered or inadequat v disposed. Inadequately disposed waste is not 8r mally managed and includes disposal in dump or open, uncontrolled landfills, where it is not fully containe Mismanaged waste could even-

ocean was 6.4 million tons [5.8 million metricass of debris entering the marine environ resutts cannot be easily extrapolated to a global scale.

Plastics have become increasingly dominantlere we present a framework to calculate the College of Engineering, University of Georgia, 412 Difference consumer marketplace since their commount of mismanaged plastic waste generated mercialdevelopment in the 1930s and 1940annually by populations living within 50 km of a Global plastic resin production reached 288 coast worldwide that can potentially enter the Atmosphere Flagship, Commonwealth Scientific and million MT in 2012 (3), 620% increase sinceocean as marine debris. For each of 192 coastal Industrial Research Organization, Castray Esplanade, 1973 he largest market sector for plastic resountries with at least 100 permanent residents ins is packaging (3); that is, materials desigtheat border the AtlanticPacific, and Indian refigitymmediate disposal. In 1960, plastics maxdeans and the Mediterranean and Black seas, up less than 1% of municipal solid waste bytheafsamework includes: (i) the mass of waste Engineering and Materials Science, Michigan State University United States (4); by 2000, this propageinerated per capita annually; (ii) the percentincreased by an order of magnitum 2005, age of waste that is plastic; and (iii) the percentplastic made up at least 10% of solid wastedage of plastic waste that is mismanaged and,

VIRAL REPLICATION

Structural basis for RNA replication structures of NS5B in both primed iniby the hepatitis C virus polymer as traditional approaches failed to yield ternary complexes (see the supplementary mate

Todd C. Appleby, 1x Jason K. Perry, 1 Eisuke Murakami, 1 Ona Barauskas, 1 Joy Feng, 1 Aesop Cho, David Fox III, Diana R. Wetmore, Mary E. McGrath, Adrian S. Ray, 1 Michael J. Sofia, ¹S. Swaminathan, ¹Thomas E. Edwards²*

Nucleotide analog inhibitors have shown clinical success in the treatment of hepatitis C virus (HCV) infection, despite an incomplete mechanistic understanding of NS5B, the viral RNA-dependent RNA polymerase. Here we study the details of HCV RNA replication by determining crystal structures of stalled polymerase ternary complexes with enzymes, We hypothesized that a triple resistance NS5B RNA templates, RNA primers, incoming nucleotides, and catalytic metal ions during both primed initiation and elongation of RNA synthesis. Our analysis revealed that highly conserved active-site residues in NS5B position the primer for in-line attack on the incoming nucleotide. A b loop and a C-terminal membrane-anchoring linker occlude the active-site cavity in the apo state, retract in the primed initiation assembly to enforce replication of the HCV genome from the 3terminus, and vacate the active-site cavity during elongation. We investigated the incorporation of nucleotide analog inhibitors, including the clinically active metabolite formed by sofosbuvir, to elucidate key molecularthe structural rearrangement observed in binary interactions in the active site.

epatitis C virus (HCV) is a positive-senpelymerase (RdRp), supports a staggering rabbed incorporate native and nucleotide analog single-stranded RNA virus of the family iral production estimated to be 1.3 \times^{12} Moiviridae and genus Hepacivirus andons produced per day in each infected patiletermination (fi&1).The use of nucleotide e cause of hepatitis C in humans ((¼)).Because the NS5B polymerase active sit@ipshosphate substrates rather than nucleotide Low-term infection with HCV can leachtighly conserved, nucleotide analog inhibitorisphosphates (fig. To gain insight into the mechanism of HCV RNA replication and its inhibition by nucleotide ana-

rials), we prepared multiple stalled enzyme-RNAnucleotide ternary complex structures containing several designed features. First, we used NS5B from the JFH-1 genotype 2a isolate of HCV, which is extraordinarily efficient at RNA synthesis (13). Second, we exploited a conformational stabilization strategy that had been developed for structural analysis of G protein-coupled receptors (14 mutant isolated under selective pressure of a guanosine analog inhibitor that exhibits 1.5 times the initiation activity of the wild type (15) might stabilize a specific conformational state along the initiation pathway. Indeed, this triple mutant exhibits a substantial structæarrangement of the polymerase (1/25)ich is consistent with complexes of a b-loop deletion mutant bound to primer-template RNA (16). The triple mutant was inhibitors with the RNA samples used in structure
